Abstract

Binaural listening is growing fast, because of growing sales in smartphones, tablets and other individual entertainment systems. The lack of a standard for the exchange of head-related transfer functions (HRTF) means each company keeps its binaural capture and rendering algorithms private. 3D audio is arising, and binaural listening could be the very first 3D audio vector with sufficient fidelity of HRTF.

The use of convolution-based reverberation processors in 3D virtual audio environments has grown with the increase in available computing power. Convolution-based reverberators guarantee for an authentic and natural listening experience, but also depend on the acoustic quality of the applied directional room impulse response (DRIR).

With a standardized file format for HRTF and DRIR data, each company could contribute its best algorithms, providing good personalized capture and/or rendering, allowing the consumer to choose its best combination of technologies for the best quality of experience.

This document standardizes a file format to exchange space-related acoustic data, such as binaural listening parameters in the form of head related transfer functions. The format will be scalable to match the available rendering process. The format will be designed to include source materials from different databases.

An AES standard implies a consensus of those directly and materially affected by its scope and provisions and is intended as a guide to aid the manufacturer, the consumer, and the general public. The existence of an AES standard does not in any respect preclude anyone, whether or not he or she has approved the document, from manufacturing, marketing, purchasing, or using products, processes, or procedures not in agreement with the standard. Prior to approval, all parties were provided opportunities to comment or object to any provision. Attention is drawn to the possibility that some of the elements of this AES standard or information document may be the subject of patent rights. AES shall not be held responsible for identifying any or all such patents. Approval does not assume any liability to any patent owner, nor does it assume any obligation whatever to parties adopting the standards document. Recipients of this document are invited to submit, with their comments, notification of any relevant patent rights of which they are aware and to provide supporting documentation. This document is subject to periodic review and users are cautioned to obtain the latest edition.

Foreword

This foreword is not part of the AES69-2015 - *AES standard for file exchange - Spatial acoustic data file format*.

This standard builds upon an earlier project to define a spatially-oriented format for acoustics (SOFA). The SOFA project considered the requirements for a file format storing HRTF data and other spatial descriptions of acoustic systems. SOFA aimed at storing data representing HRTF data in a general way, capable of supporting any data measured with microphone arrays and loudspeaker arrays.

This project was developed as project AES-X212 by Task Group SC-02-08-E led by M. Parmentier. The principal authors were P. Majdak and M. Noisternig.

The following persons were involved in the development of this document in draft:

T. Ammermann, S. Bharitkar, F. Camerer, W. De Bruijn, T. Carpentier, M. Emerit, F. Fleischmann, K. Hamasaki, A. Harma, J-M. Jot, M. Kelly, R. Kessler, T. Knowles, P. Majdak, F. Melchior, M. Noisternig, B. Olson, G. Pallone, C. Par, M. Parmentier, A. Pereira, C. Pike, J. Plogsties, E. Ronciere, T. Sporer, B. van Daele, W. Woszczyk, H. Ziegelwanger

Mark Yonge
Chair, SC-02-08 Working Group on Audio-File Transfer and Exchange

Note on normative language

In AES standards documents, sentences containing the word “shall” are requirements for compliance with the document. Sentences containing the verb “should” are strong suggestions (recommendations). Sentences giving permission use the verb “may”. Sentences expressing a possibility use the verb “can”.

AES standard for file exchange - Spatial acoustic data file format

0 Introduction

0.1 General

A spatial acoustic transfer function describes the spatial filtering of the incoming sound, due to the listener's anatomy for example. Previously, spatial-acoustic data have been stored in various incompatible formats, making an exchange of this data difficult. This document describes a format for storing spatial acoustic data with a focus on interchangeability and extensibility and provides a basis for a wider generalised interchange of space-related audio data.

In this document, the term 'transfer function' (TF) describes any filter, regardless the actual representation or interpretation. TF may, for example, refer to:

- The frequency domain representation of free-field head-related transfer functions (HRTFs);
- The time domain representation of free-field HRTFs, that is head-related impulse responses (HRIRs);
- The time domain representation of HRTFs measured in reverberant spaces, that is binaural room impulse responses (BRIRs);
- The Quadrature Mirror Filter (QMF) domain representation of free-field HRTFs, that is the set of QMF parameters; or, even more generally,
- The time domain representation of spatiotemporal room impulse responses, that is directional room impulse responses (DRIRs).

If not otherwise stated, we do not distinguish between such terminologies and refer to all those filters as transfer functions.

Specifications given in 'conventions' (that is in-detail descriptions of the data exchange format for a given data set) shall use the correct terminology, for example using HRIR instead of HRTF when the data are represented in time domain.

The following requirements are identified:

- Description of a measurement setup with arbitrary geometry; that is, not limited to special cases like a regular grid, or a constant distance;
- Self-describing data with a consistent definition; that is, all the required information about the measurement setup must be provided as metadata in the file;
- Flexibility to describe data of multiple conditions (listeners, distances, and so on) in a single file;
- Partial file support and network support;
- Available as binary file with data compression for efficient storage and transfer;
- Predefined descriptions for the most common measurement setups, which are referred to as 'conventions'.

A TF measurement setup is described by various objects (4.2) and their relations (4.3); the information is stored in a numeric container (4.4) and structured by the measurement.

A measurement consists of data (4.6) describing a TF for a single condition, for example an HRIR, and is described by its corresponding dimensions (4.5) and metadata (4.7). All measurements are stored in a single

data structure. Conventions for a consistent description of measurement setups are provided in annex D of this document.

0.2 Documentation conventions

A Courier typeface is used in this document to identify computer listing examples to distinguish them from regular text.

1 Scope

This document standardizes a file format to exchange space-related acoustic data in various forms. The format is designed to be scalable to match the available rendering process. The format is designed to be sufficiently flexible to include source materials from different databases.
