

# **In-Vehicle Audio System Distortion Audibility versus Level and Its Impact on Perceived Sound Quality**

Patrick Dennis – Nissan  
Steve Temme – Listen Inc.

Presented at AES 141 Los Angeles, 2016

## Inspiration for Study

- Temme et. al. studied distortion audibility in headphones and its relation to listener preference in paper "The Correlation Between Distortion Audibility and Listener Preference in Headphones" 137<sup>th</sup> AES preprint no. 9118
- THD (Total Harmonic Distortion), IMD (Intermodulation Distortion) and NCD (Non-Coherent Distortion) metrics were compared to listener subjective preferences and found that the NCD metric had the best correlation
- This paper focuses on In-Vehicle audio systems because their distortion is typically higher than headphones
- The equalization and description challenges faced with headphones were eliminated by using the same audio system and recording at different volume levels to achieve different levels of distortion

Program/Artist/Track/Album	Description
AB - Estelle w. Kanye West/ American Boy Shine/ Atlantic Records, 2008	Male/Female Hip Hop
BW - Jennifer Warnes/Bird on a Wire/Famous Blue Raincoat/ Cypress Records, 1986	Female Pop Vocal
CD - Steely Dan/Cousin Dupree/Two Against Nature/ Giant Records/ 2000	Male Pop Vocal

## Program Selections

## Test Setup – Binaural Recordings

- Binaural recordings (48kHz, 24 bit) were made from volume step 20 to 40 (maximum) in 2 step increments using a Head Acoustics HMS II.6 Head and Torso simulator and BEQ II front end module
- Each recording was loaded into Head Acoustics Artemis software and exported with the HSU III ID (Independent of Direction) EQ applied
- Adobe Audition was then used to match each recording for overall loudness as well as spectrum in the bass region
  - Spectrum matching in bass region needed to offset the effect of dynamic loudness in the head unit
- The adjustments helped make the distortion artifacts the main distinguishing difference between the recordings

## Test Signals for Measuring Distortion

- Swept-stepped sine
  - Easy to calibrate and indicate type of non-linearity
- Two-tone intermodulation (one fixed, one moving)
  - More fully characterize a non-linear system and sum & difference components have no harmonic musical relationships and can be quite annoying
- Pink noise
  - Fast and excites all non-linearities simultaneously, more like music
- Music – same tracks used for listening tests
  - More realistic but the music needs to have a broad frequency spectrum in order to get a good signal to noise ratio

## Fundamental vs. Volume Level

Fundamental with Stweep

1/12<sup>th</sup> Oct. Frequency response of sedan audio system measured at 11 different volume levels from average 76-102dB SPL (C-weighted)

- Usual peaks and dips inside a car due to reflections and standing waves
- There starts to be some severe compression happening at high levels and low frequencies

## THD Normalized vs. Volume Level

Total Harmonic Distortion Normalized

Harmonic Distortion, frequency normalized at their measured frequency, to remove the effect of reflections and standing waves before calculating THD.

- THD increases versus level but jumps significantly at volume 36 (100dBC) and above, especially from 200 – 700Hz

**When a pure tone is slightly above the hearing threshold, low-order harmonics can be easily heard.**

# Typical Rub & Buzz

## Resulting spectrum for a pure tone excitation (f) at 200 Hz

- Upper curve shows a distortion spectrum of a normally functioning loudspeaker. THD = 6%, Rub&Buzz = 0.02%
- Lower curve shows a distortion spectrum containing high order harmonics resulting from a “rubbing” voice coil caused by a bent frame. THD = 2%, Rub&Buzz = 0.3%

## Perceptual Rub & Buzz vs. Volume Level

Perceptual Rub & Buzz

Perceptual Rub & Buzz in phons for better correlation to human hearing (AES 127th Convention, preprint 7905)

- Audible distortion above volume 34 (26 phons)
- Hard to tell if buzzing is coming from the speakers, door panels, center console, rear parcel shelf or a combination there of

## NCD Distortion (American Boy) vs. Level

AB Non-Coherent Distortion

NCD with Estelle music as the test signal. The average SPL for volume level 30 was a loud 105dBC!

- Distortion curve shapes are similar with the previous songs but the distortion jumps at volume level 24 and above. This is probably due to the higher recording level

## Conclusions

- Music material and volume level were significant compared to listener age and experience for perceived severity
- This car audio system sounds noticeably distorted with most music above 100dBC in the frequency range of 200 – 2kHz and above 0.2% NCD
- American Boy with its highly compressed and distorted recording made it more difficult to discern distortion threshold because it sounded distorted to begin with
- Probably most of the distortion heard was high order distortion from Rub & Buzz
- Non-coherent distortion using music as a stimulus showed better correlation to human perception than traditional harmonic and intermodulation distortion measurements
